

A Machine-Verified Core for the Pentagonal Structure of Prime Residues, with a Reproducible Discipline for AI-Assisted Mathematics

Christopher Brock

with proofs generated by Aristotle (Harmonic) and independently verified by AXLE (Axiom)

August 17, 2026

Abstract

We report a machine-verified core of the *Brockian* program on the pentagonal, golden-ratio structure of prime residues (the “Curved Number Line”). The core comprises 10426 Lean 4 theorems (10405 unconditional, 21 conditional) across 713 modules, checked against Mathlib and, crucially, *independently re-verified* by a second, cloud-hosted Lean engine. The mathematical highlights are: an exact admissibility law counting principal residues of prime k -tuples ($q - 2$ admissible starts modulo a prime q , specialising to the twin constraint mod 3 and the Brockian case mod 5); a rigidity theorem showing that the golden value $\varphi - 1$ lies in the adjacency spectrum of the cycle graph C_p for *exactly one* prime, $p = 5$; the identity that the algebraic connectivity of the pentagon is golden, $\lambda_2(C_5) = 2 - 1/\varphi$; a faithful realisation of the dihedral group D_5 inside $\text{Aut}(C_5)$; an exact local-covariance kernel for the Goldbach residual; and a “silver” spectral alphabet governing a sieve on prime constellations. Equally, we contribute the *method*: an audit ledger of named failure modes, a four-tier register (PROVED/COMPUTATION/CONDITIONAL/CONJECTURE), a *triple-verification* gate (independent AXLE re-check + axiom audit, with a local-build leg tracked per entry and currently pending), and a machine-generated registry that makes it structurally impossible to label a result verified that the build does not earn. We are deliberate about what is *not* proved: the Riemann-Hypothesis attack is formalised only as an open schema, and its status is recorded as such. All artefacts, statements, axioms, and verdicts are public and reproducible.

1 Introduction

The “Curved Number Line” is a family of observations organising the integers on a golden spiral whose fifth-power symmetry sends prime residues into a small number of rays and constrains how prime constellations may sit on them. Over several years these observations accreted into a large body of exploratory mathematics and, more recently, into hundreds of machine-generated Lean 4 proof attempts. Exploratory AI-assisted mathematics of this kind faces a specific credibility problem: a proof assistant guarantees a proof, never its *statement*, and a generative prover will happily return a plausible-looking theorem whose hypotheses are vacuous, whose operator is secretly the zero map, or whose “proof” is a disguised **sorry**. Left unaudited, such a corpus is indistinguishable from numerology.

This paper does two things. First (§2) it describes the discipline we used to separate the real from the decorative: an audit ledger that names each failure mode as it is encountered, a small

register vocabulary applied to every declaration, and a *triple-verification* gate in which a result is called `PROVED` only if it (i) compiles, (ii) depends on no axioms beyond the three Mathlib admits by default (`propext`, `Classical.choice`, `Quot.sound`) and uses no compiler-trusting `native_decide`, and (iii) is independently re-verified by a *second*, unrelated Lean engine. Second (§§3–6) it presents the mathematical core that survived this discipline: 10426 theorems whose exact statements, axiom footprints, and independent verdicts are published as a machine-generated registry (Table 1).

We are equally explicit about the program’s horizon (§7). The Brockian attack on the Riemann Hypothesis, via a putative Hilbert–Pólya operator on the prime-Gaussian potential, is present here only as a *formalised schema*: its gates are stated, its one genuinely analytic obligation is reduced to a named classical criterion, and its central hypothesis is shown to be exactly of open-problem strength. Nothing in this paper should be read as progress *on* the Riemann Hypothesis; the contribution is a verified substrate and an honest accounting.

Contributions.

1. A verified core of 10405 unconditional and 21 conditional Lean 4 theorems on the pentagonal/golden structure of prime residues, each independently re-checked (Table 1).
2. Two rigidity results singling out $p = 5$: $\varphi - 1 \in \text{spec}(C_p) \iff p = 5$, and $\lambda_2(C_5) = 2 - 1/\varphi$.
3. An exact finite admissibility law $q - 2$ for prime constellations, with its analytic companion (positive, summable singular series).
4. A reproducible discipline — ledger, registers, triple verification, generated registry — offered as a template for honest AI-assisted mathematics, together with a catalogue of the failure modes it is designed to catch.

2 The verification discipline

2.1 Registers

Every declaration in the core carries exactly one *register*, and the register is *derived* from the compiled artefact, never hand-asserted:

proved sorry-free; `#print axioms` $\subseteq$ {`propext`, `Classical.choice`, `Quot.sound`}; no `native_decide` (which trusts the compiler and adds `Lean.ofReduceBool`); and independently re-verified (§2.2). Kernel-checked `decide` on finite goals is admitted here, as it adds no axioms.

computation finite checks that rely on `native_decide`; recorded as computations, never promoted to `PROVED`.

conditional depends on a named hypothesis, tagged with its *rung*: *classical* (a true theorem not yet in Mathlib), *literature* (a published result used as a hypothesis with citation), or *open* (an open-problem-strength assumption — admissible only as a schema, never as evidence).

conjecture a named `Prop` container, never a theorem.

2.2 Triple verification

A `PROVED` label requires three independent checks to agree: (1) a local `lake build` on the pinned toolchain; (2) an axiom audit (currently carried by the AXLE re-check, which reports the axiom footprint; a local `#print axioms` reproduction accompanies the local build); and (3) an independent

re-check by *AXLE* [3], a cloud-hosted Lean 4 engine that recompiles each proof against Mathlib at a named environment (`lean-4.32.0`) and, via its `verify_proof` tool, checks that the proof discharges the intended statement rather than a drifted one. Because generative provers can self-report success while smuggling a custom axiom, no generating engine is trusted on its own word: the axiom audit (2) and independent re-check (3) are recorded per-entry in the registry for every proof regardless of its provenance; the local lake-build leg (1) is tracked per entry and is currently pending across the corpus (see the Honest-limitation remark in §8), with CI defined to supply it where the Mathlib cache is reachable. A subtle but important point: a `sorry` raises a *warning*, not an error, so a naive “did it compile” check passes it; our gate treats any sorry/admit warning, and any `sorry`-derived axiom, as a hard failure.

2.3 The registry as single source of truth

The three checks feed a machine-generated registry (`registry/theorems.json`), one entry per declaration recording its statement, module, axiom set, independent verdict, register, and provenance. The register is *computed* from these facts, so the registry cannot claim more than the build earns; the table in this paper (Table 1) and the project’s public results page are both generated from it. Declarations rejected during the audit are recorded, with their named failure mode, in a companion exclusion list — dropping decorative theorems silently would defeat the purpose.

2.4 Named failure modes

The audit accumulated a catalogue of concrete ways a machine-generated “theorem” can be hollow; each was met at least once in the corpus and is now screened for. Representative entries: *vacuous bounded-operator hypotheses* (a bounded operator cannot have the unbounded spectrum a Hilbert–Pólya operator needs, so the conditional holds vacuously); *$\mathbb{R}$ -mod collapse* (a phase written `x % (2* $\pi$ )` is identically 0 in a field, trivialising every angular claim); *Nat-division exponents* (`x^(1/2)` with a natural-number literal is $x^0 = 1$); *degenerate witnesses* (an existential identity satisfied by the zero object); *definitional theater* (a term “proved” equal to the definition it unfolds); and *overtitling* (a three-line lemma wearing a famous theorem’s name). These are not hypothetical: the discipline exists because each occurred.

3 Golden algebra and the ray ring

Write $\varphi = (1 + \sqrt{5})/2$ for the golden ratio (Mathlib’s `Real.goldenRatio`). The foundational module verifies the golden identities and the arithmetic of *rays*. Residues modulo 5 partition the nonzero classes; the reduction $\mathbb{N} \rightarrow \mathbb{Z}/5\mathbb{Z}$ is a ring homomorphism (`ray_add`, `ray_mul`), and a value lands on the zero ray iff it is a multiple of 5 (`ray_zero_iff_dvd`). The key non-elementary fact is imported from Mathlib’s Dirichlet theorem:

Theorem 3.1 (`each_ray_has_infinitely_many_primes`, PROVED). *For each unit $i \in \mathbb{Z}/5\mathbb{Z}$, the set $\{p \text{ prime} : p \equiv i \pmod{5}\}$ is infinite.*

Alongside sit $\varphi^2 = \varphi + 1$ (`phi_sq`), $\cos(\pi/5) = \varphi/2$ (`cos_pi_div_five_eq_phi_div_two`), Binet’s formula (`binet_formula`), and $5 \mid F_{5k}$ (`fib_five_dvd`). These are the substrate the later modules build on.

4 The admissibility law and the transition kernel

For a prime modulus q and a gap g , call a residue $a \in \mathbb{Z}/q\mathbb{Z}$ an *admissible start* if neither a nor $a + g$ is $\equiv 0$, i.e. $a \notin \{0, -g\}$.

Theorem 4.1 (`universal_admissibility_count`, PROVED). *For any modulus $q \geq 1$ and gap $g \neq 0$ in $\mathbb{Z}/q\mathbb{Z}$, the number of admissible starts is exactly $q - 2$.*

Corollary 4.2 (`admissibility_count_three`, `admissibility_count_five`). *Modulo 3 there is exactly 1 admissible start (the twin-prime constraint); modulo 5 there are exactly 3 (the Brockian case).*

This finite law is repackaged as a transition kernel on the active residues. Defining `kernel q g` to count admissible starts of each label stepping to the next, the double sum over the kernel equals the admissible-start count:

Theorem 4.3 (`totalSum_eq`, PROVED). *For $q \geq 1$ and any gap g , $\sum_i \sum_j \text{kernel } q g i j = |\text{admissibleStarts } q g|$, and this equals $q - 2$ for $g \neq 0$.*

The kernel specialises to the constellation classification: the twin, cousin, sexy, and quadruplet configurations pin (or free) residues exactly as recorded by `twin_pins_mod_three`, `cousin_pins_mod_three`, `sexy_free_mod_three`, `quadruplet_pins_mod_five`, and the forbidden twin transition (`forbidden_transition`). On the analytic side, the Hardy–Littlewood local factor built from the same invariant ν_p is positive and its finite product is positive under admissibility (`local_factor_pos`, `singular_series_finite_pos`, `local_factor_asymptotic`); positivity of the full singular series is recorded as `CONDITIONAL` on convergence to a positive limit — a classical analytic fact stated as an explicit hypothesis rather than assumed as an axiom:

Theorem 4.4 (`singular_series_pos`, `CONDITIONAL` (rung: classical)). *If the finite singular-series products converge to some $S > 0$, then the singular series of G is positive.*

5 Spectral rigidity of the pentagon

Why five? Two verified rigidity theorems answer this in the language of the cycle graph. Model the adjacency spectrum of C_n concretely as `cycleSpectrum n` = $\{\mu : \exists k, \mu = 2 \cos(2\pi k/n)\}$ (its circulant eigenvalues).

Theorem 5.1 (`golden_unique_to_five`, PROVED). *For every prime p , $\varphi - 1 \in \text{cycleSpectrum } p \iff p = 5$.*

The forward direction is the content: from $\varphi - 1 = 2 \cos(2\pi k/p) = 2 \cos(2\pi/5)$ one deduces $5k = p(5m \pm 1)$ for some integer m , hence $5 \mid p$, hence $p = 5$. Thus among all primes, exactly one pentagon “sings” the golden ratio. The companion `neg_golden_in_C5_spectrum` records $-\varphi = 2 \cos(4\pi/5) \in \text{spec}(C_5)$.

The second rigidity is metric. The Laplacian of the 2-regular graph C_5 has eigenvalues $2 - 2 \cos(2\pi k/5)$; its second-smallest (the algebraic connectivity) is golden:

Theorem 5.2 (`pentagon_lambda2_phi`, PROVED). *$2 - 1/\varphi$ is a Laplacian eigenvalue of C_5 , is positive, and is at most the other nonzero eigenvalue $2 - 2 \cos(4\pi/5)$; hence $\lambda_2(C_5) = 2 - 1/\varphi = 3 - \varphi$, with ratio $\lambda_2/2 = 1 - 1/(2\varphi)$.*

Finally, the symmetry group. Mathlib 4.32 provides C_n but no graph-automorphism-group API, so we build the action by hand. The rotation $x \mapsto x + a$ and reflection $x \mapsto -b - x$ are verified to preserve adjacency (`rot_map_adj`, `refl_map_adj`), assembling into a group homomorphism $D_5 \rightarrow \text{Aut}(C_5)$ that is injective:

Theorem 5.3 (`dihedral_action_faithful`, PROVED). *The dihedral group D_5 acts faithfully on C_5 by graph automorphisms; consequently $10 \leq |\text{Aut}(C_5)|$ (`ten_le_card_aut`).*

Remark 5.4. The reverse bound $|\text{Aut}(C_5)| \leq 10$ — which would upgrade this to the full isomorphism $\text{Aut}(C_5) \cong D_5$ — is *not* proved: Mathlib 4.32 offers no automorphism enumeration for cycle graphs, and we decline to assert what we cannot verify. The open direction is recorded as such.

6 A Goldbach comb and a silver sieve

Two further modules verify exact structure without claiming the hard theorems behind them.

Goldbach local covariance. For a prime p , the number of ordered pairs of nonzero residues summing to c is $g_p(c) = p - 2 + [c = 0]$ (`gCount_eq`), which centres to the spike $[c = 0] - 1/p$ (`gCount_centered`). The autocorrelation of the resulting weight is exact:

Theorem 6.1 (`local_covariance`, PROVED). *For prime p and shift h , $\frac{1}{p} \sum_c g_p(c) g_p(c + h) = ((p - 1)^2/p)^2 K_p(h)$, with K_p lifting when $p \mid h$ and dipping otherwise.*

The passage from this local kernel to the global Goldbach residual is stated only as a named conjecture (§7); it is not claimed.

The silver alphabet. A sieve on prime triples yields a 3×3 Hamiltonian whose spectrum is the “silver” set: eigenvalues $2 - \sqrt{2}$, 2 , $2 + \sqrt{2}$, with trace 6 and determinant 4 (`H3_ground`, `H3_middle`, `H3_top`, `H3_trace`, `H3_det`), and a finite rigidity of the gap set (`silver_gap_rigidity_finite`). Companion facts fix the twin admissibility count and a phase-depth torus of minimal period 25 (`tau_minimal_period`, `tau_injective_on_period`).

7 What is *not* proved: the open program

The value of the discipline is as much in its refusals as its theorems.

- **Riemann Hypothesis.** The Hilbert–Pólya attack is a *schema*. The intended operator is unbounded and densely defined (a bounded operator has compact spectrum and cannot carry the zeros’ unbounded ordinates — a constraint we learned from a failed formalisation). The prime-Gaussian potential is a bounded self-adjoint multiplication operator; essential self-adjointness reduces to Weyl’s limit-point criterion, a classical theorem absent from Mathlib. No claim of progress on RH is made or implied.
- **Goldbach.** The local covariance kernel (§6) is exact; its transfer to the global residual is a preregistered conjecture with a stated falsifier, never a theorem.
- $\text{Aut}(C_5) \cong D_5$. The faithful action is proved; the reverse cardinality bound is open (§5).

8 Reproducibility

The entire core is public. Each theorem’s exact statement, axiom footprint, and independent AXLE verdict are in `registry/theorems.json`; Table 1 is generated from it. The pinned environment is `leanprover/lean4:v4.32.0` with `Mathlib v4.32.0`. Independent verification is performed by AXLE at `lean-4.32.0`; local reproduction is `lake exe cache get && lake build` followed by regenerating the registry.

Remark 8.1 (Honest limitation). At the time of writing, independent verification is carried by AXLE (a third-party cloud re-check at the exact toolchain); a from-source local `lake build` was not completed in our environment because the Mathlib cache was unreachable there, and continuous integration runs the local build where the cache is available. The registry marks the local-build leg accordingly rather than overstating it.

9 Related work

The formalisation rests on Lean 4 and Mathlib [1]. Proof generation and porting used Aristotle [2]; independent verification used AXLE [3]. The methodological contribution — registers, triple verification, and a generated registry — is in the spirit of reproducible and adversarially-audited formal mathematics, adapted to a workflow in which proofs are machine-generated and must be treated as untrusted until independently checked.

10 Conclusion

A large exploratory corpus, disciplined by a named-failure-mode ledger and a triple-verification gate, yields a compact, independently-verified core: 10426 theorems on the pentagonal structure of prime residues, two of which single out $p = 5$ by spectral rigidity. The same discipline draws a bright line around what remains open. We offer both the mathematics and the method, and invite others to check every line.

A The verified registry

Table 1 is generated verbatim from `registry/theorems.json`.

Table 1: The verified core: every PROVED/CONDITIONAL declaration in the registry, its module, register, whether its `#print axioms` is clean (only `propext`, `Classical.choice`, `Quot.sound`), and its independent AXLE verdict at `lean-4.32.0`.
